Problem formulation:

 $\min[c^{T}x] - [x^{T}Qx]$  $[s.t. Ax \sim b]$  $[x^{T}Q_{i}x \sim b_{i}]$  $x_{B} \in \{0,1\}$ 

// no assumptions on convexity of  $x^T Q x$ 

// mostly interested in all binary variable case

- Possibly nonconvex MIQ(C)P
- Can reformulate constraints into objective using penalties (QUBO)
  - Good formulation for Quantum Annealers, but Gurobi usually works better on original formulation
  - <u>https://www.springerprofessional.de/en/quantum-bridge-analytics-i-a-tutorial-on-formulating-and-using-q/17436666</u>

- The Standard Linearization (Fortet, 1959; Watters, 1967)
  - Linearize a convex or nonconvex MIQP into a MILP
    - Simplest linearization technique: do the following for each product of binaries in the model (PreQLinearize=1)

• 
$$Z_{ij} = x_i x_j$$
  
 $Z_{ij} \le x_i$   
 $Z_{ij} \le x_j$  (only need these two if objective pushes  $z_{ij}$  up)

 $z_{ij} \ge x_i + x_j - 1$  (only need this one if objective pushes  $z_{ij}$  down)

- Add the 3 linear constraints to the model
- Replace each occurrence of  $x_i x_j$  in the model with  $z_{ij}$
- We've transformed a (possibly nonconvex) MIQP into a MILP
  - Benefit from various Gurobi features available for MILP but not MIQP
  - Still no free lunch
    - We added 1-3 constraints and one new variable for each product of binaries.

© 2023 Gurobi Optimization, LLC. Confidential, All Rights Reserved | 6

- What about the product of a binary and a continuous (or general integer)?
  - This will help us later with linear combinations of products of binaries

- A less straightforward but more compact linearization technique (Glover 1975)
  - Works when a single binary appears in multiple products of binaries
  - Gurobi's PreQLinearize = 2 setting uses this to do a more compact linearization
  - $q_1y * x_1 + \dots + q_ny * x_n$  (y,  $x_j$  binary) is rewritten as  $(q_1x_1 + \dots + q_nx_n) * y = z$ 
    - Product of continuous and binary
    - Bounds on continuous variable derived from the  $q_i$  coefficients
      - Simplest case:  $L = 0 U = \sum_{j=1}^{n} q_j$  when  $q_j > 0$ .
  - Replace every occurrence of  $q_1y * x_1 + \dots + q_ny * x_n$  with z
  - Added 4 constraints and one variable for the n bilinear terms associated with y
    - Instead of up to 3n constraints and n variables with the standard linearization

- A variant of Glover's linearization
  - Based on specialized soft knapsack constraints
    - Example (simplified from neos-911970)

#### Minimize

C0001 + C0002 + C0003 + C0004 + C0005 + C0006 + C0007 + C0008 + C0009 + C0010 + C0011 + C0012 + C0013 + C0014 + C0015 + C0016 + C0017 + C0018 + C0019 + C0020 + C0021 + C0022 + C0023 + C0024 + **C0025** + C0026 + C0027 + C0028 + C0029 + C0030 + C0031 + C0032 + C0033 + C0034 + C0035 + C0036 + C0037 + C0038 + C0039 + C0040 + C0041 + C0042 + C0043 + C0044 + C0045 + C0046 + C0047 + C0048 Subject To

Knapsack capacity matches largest knapsack weight

R0001a: - C0025 + 4.2 B0673 + <u>6.5 B0697</u> + 5.95 B0721 <= 6.5

B0673 = B0697 = 1 --> C0025 = 4.2 + 6.5 - 6.5 = 4.2 B0673 = B0721 = 1 --> C0025 = 4.2 + 5.95 - 6.5 = 3.65 B0697 = B0721 = 1 --> C0025 = 6.5 + 5.95 - 6.5 = 5.95 B0673 = B0697 = B0721 = 1 -> C0025 = 4.2 + 5.95 = 10.15 Could modify the coefficients to extend do handle larger multilinear terms

Could also modify to handle only bilinear terms

R0001a provides a linear representation of C0025 = 4.2 B0673\*B0697 + 3.65 B0673\*B0721 + 5.95 B0697\*B0721 - 3.65 B0697\*B0673\*B0721

- A more compact linearization for sum of bilinear terms sharing a common variable
  - R0001': <u>- C0025</u> + 5.43 B0049 + 5.56 B0073 + 5.2 B0097 + 5.4 B0121 + 5 B0145
  - + 4.39 B0169 + 4.07 B0193 + 4.56 B0217 + 4.03 B0241 + 3.3 B0265
  - + 4.39 B0289 + 5.64 B0313 + 5.9 B0337 + 3.57 B0361 + 6.4 B0385
  - + 3.94 B0409 + 4.5 B0433 + 4.67 B0457 + 3.88 B0481 + 4.18 B0505
  - + 4.31 B0529 + 4.63 B0553 + 4.74 B0577 + 5.5 B0601 + 5.1 B0625
  - + 5.1 B0649 + 4.2 B0673 + <u>166.76 B0697</u> + 5.95 B0721 + 5.88 B0745
  - + 5.77 B0769 + 5.36 B0793 + 5.64 B0817 + 5.04 B0841 + 5.53 B0865 <= **<u>166.76</u>**

166.76 = sum of all knapsack weights except for B0697

- All sums of knapsack weights other than B0697 will be <= the rhs
  - $\rightarrow$  all multilinear expressions not involving B0697 contribute 0 violation to this soft constraint
- If B0697 = 1 and any other binary variable = 1 we get a contribution of the other binary variable's coefficient to the violation (e.g B0049 = 1 contributes 5.43 of violation).
- C0025= 5.43 B0049\*B0697 + 5.56 B0073\*B0697 + ... + 5.53 B0865\*B0697
  - C0025 represents precisely a quadratic expression involving B0697 and other binaries
  - More compact than standard linearization when one binary variable appears in multiple bilinear terms
  - Works for bilinear terms in the objective but not in the constraints

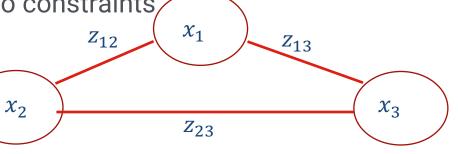

- A less straightforward but more compact linearization technique
  - C0025= 5.43 C0049\*C0697 + 5.56 C0073\*C0697 + ... + 5.534 C0865\*C0697
    - C0025 represents precisely a quadratic expression involving C0697 and other binaries
  - $q_1y * x_1 + \dots + q_ny * x_n (y, x_j binary)$  is linearized as  $q_1x_1 + \dots + q_nx_n + qy - p \le q \qquad (q = \sum_{j=1}^n q_j) \qquad //q_j > 0.$
  - Replace every occurrence of  $q_1y * x_1 + \dots + q_ny * x_n$  with p
  - Add the soft knapsack constraint
  - Added one constraint and one variable for the n bilinear terms associated with y

#### GUROBI OPTIMIZATION

- Summary of Gurobi PreQLinearize settings: No Free Lunch
  - PreQLinearize = 0: Convexify the nonconvex quadratic objective
    - Move from nonconvex MIQP to convex MIQP $\stackrel{l}{
      m de}$
    - No additional constraints
    - Miss out on MILP features absent from convex MIQP solver
    - Counterintuitive dual bound values that suggest possibly weak relaxations
  - PreQLinearize = 1: Linearize the nonconvex quadratic objective with new variable and constraints for each bilinear objective term
    - Move from nonconvex MIQP to MILP $\stackrel{l}{\leftarrow}$ 
      - Fairly strong MILP formulation
    - Each bilinear term in the quadratic objective introduces one new variable and 1-3 additional linear constraints
  - PreQLinearize = 2: Use Glover's Linearization
    - Move from nonconvex MIQP to MILP  $\stackrel{\downarrow}{
      m de}$
    - Multiple bilinear terms modelled with one additional variable and 4 constraints
    - Weaker MILP formulation

#### GUROBI OPTIMIZATION

- Padberg, The Boolean Quadric Polytope: Some Characteristics, Facets and Relatives
  - Product graph associated with products of binary variables and the standard linearization
  - Generate cuts even when the original problem has no constraints
    - Example:  $x_1 + x_2 + x_3 (z_{12} + z_{23} + z_{13}) \le 1$
    - Can prove by contradiction
    - Or by induction
      - Extends to cliques of larger size
    - Or by deriving as a zero half cut
      - But Padberg figured it out first
    - Or via facet defining inequalities
  - Gurobi's BQP cut feature makes use of this with cliques of size 3
    - Traction for cut generation when model has few or no constraints
    - Gurobi 9.5 and later also considers cliques of size 4 or more

- Given a set of n points with distances dij between points i and j, find the subset of k points that maximizes the sum of the distances
  - $Max \sum_{i < j} d_{ij} x_i x_j$ s.t.  $\sum_{j=1}^n x_j = k$  $x_j \in \{0, 1\}$
- Example discussed in Practical Guidelines for Solving Difficult MILPs (<u>https://www.sciencedirect.com/science/article/abs/pii/S1876735413000020</u>
- Broader discussion in <u>http://yetanothermathprogrammingconsultant.blogspot.com/2019/06/maximu</u> <u>m-dispersion.html</u>

- LP relaxation feasible region is the convex hull of the integer feasible points
  - Won't be able to use LP-based polyhedral cuts on this direct formulation
  - Previous results indicate just linearizing (PreQLinearize=1) is better, but still not particularly effective given the problem size
- <u>http://yetanothermathprogrammingconsultant.blogspot.com/2019/06/maximum-dispersion.html</u> describes multiple ways to derive a single cut that uses both original x binary variables and the linearization variables z
- $Max \sum_{i < j} d_{ij} x_i x_j$ s.t.  $\sum_{j=1}^n x_j = k$  $x_j \in \{0, 1\}$

 $Max \sum_{i < j} d_{ij} z_{ij}$ s.t.  $\sum_{j=1}^{n} x_j = k$ <linearization constraints>  $\sum_{i < j} z_{ij} = k * (k - 1)/2$  $x_i \in \{0, 1\}$ 

- Run time with cut drops from hours to < a minute
- Blog describes multiple ways to derive this cut, but how do we do it generically in a way that extends to other models?

Padberg graph for our dispersion problem

Complete graph since  $d_{ij} > 0$ 

 $Max \sum_{i < j} d_{ij} z_{ij}$ s.t.  $\sum_{j=1}^{n} x_j = k$ earization constraints>  $\sum_{i < j} z_{ij} = k * (k - 1)/2$  $x_i \in \{0, 1\}$ 

- Given that k of the x variables must be 1, how many of the z variables must be 1?
  - WLOG, set the first k x variables to 1
  - Induces a complete subgraph on the green nodes associated with x<sub>1</sub>, ..., x<sub>k</sub>
  - Each edge in the subgraph identifies a z variable that must be 1
  - There are k \* (k 1)/2 such edges

neos-2629914-sudost

Summary

• Minimization problem

Model belongs in QPLIB, not MIPLIB

- All objective variables have lower bounds of 11
- Constraint group 1: 16x16 grid of binaries whose row and column sums
   = 1
- Constraint groups 2 and 3 express linearizations of products of binaries variables analogous to Gurobi's PreQLinearize = 1 and 2 settings
  - Removing one of these groups has no impact on the dual bound
  - Removing both of these groups enables the model to solve instantly with all objective variables at their lower bounds of 11
- Model appears to minimize the sum of 240 different minimax functions
  - Or does it?

#### neos-2629914-sudost

Additional simplifications

...

- Does model really minimize the sum of 240 different minimax functions?
  - Let's take a closer look at the minimax functions
    - Consider group 3 constraints for C0001

R48033: C0001 - **224 B0241** + 213 B0258 + 212 B0259 + 212 B0260 + 211 B0261 + 210 B0262 + 210 B0263 + 209 B0264 + 211 B0265 + 209 B0266 + 208 B0267 + 207 B0268 + 206 B0269 + 205 B0270 + 207 B0271 + 206 B0272 >= 0 R48034: C0001 - **210 B0242** + 199 B0257 + 199 B0259 + 199 B0260 + 198 B0261 + 197 B0262 + 197 B0263 + 196 B0264 + 198 B0265 + 196 B0266 + 195 B0267 + 194 B0268 + 193 B0269 + 192 B0270 + 194 B0271 + 193 B0272 >= 0

R48048: C0001 - **212** <u>B0256</u> + 194 B0257 + 195 B0258 + 196 B0259 + 196 B0260 + 197 B0261 + 198 B0262 + 198 B0263 + 199 B0264 + 195 B0265 + 199 B0266 + 200 B0267 + 199 B0268 + 200 B0269 + 201 B0270 + 201 B0271 >= 0 Each constraint selects one variable from row 1 of the grid, considers its bilinear terms with all variable in row 2 of the grid

Exactly one bilinear term from all 16 constraints will have xi\*xj = 1 (xi from grid row 1; xj from grid row 2)

#### GUROBI OPTIMIZATION

# **Additional Simplifications**

 $C0001 \ge q_{ij}x_ix_j \quad i \in G1, j \in G2$   $(only \ 1 \ x_ix_j = 1)$   $C0001 \ge \sum_{i \in G1} \sum_{j \in G2} q_{ij}x_ix_j$   $[11,inf) \quad [0,U] \qquad Dual argument; C0001 intersects no other group 3 constraints$   $C0001 = \sum_{i \in G1} \sum_{j \in G2} q_{ij}x_ix_j$ Remove group 3 constraints for C0001, put this equality in the objective

Minimize

 $\begin{array}{c} 13 \sum_{i \in G1} \sum_{j \in G2} q_{ij} x_i x_j + 14 \ \text{COOO2} + 16 \ \text{COOO3} + 18 \ \text{COOO4} + 15 \ \text{COOO5} + 16 \ \text{COOO6} + 16 \ \text{COOO7} \\ + 15 \ \text{COO08} + 11 \ \text{COOO9} + 14 \ \text{COO10} + 16 \ \text{COO11} + 11 \ \text{COO12} + 15 \ \text{COO13} \\ + 14 \ \text{COO14} + 15 \ \text{COO15} + 13 \ \text{COO16} + 16 \ \text{COO17} + 13 \ \text{COO18} + 17 \ \text{COO19} + \dots \\ \dots + 15 \ \text{CO224} + 18 \ \text{CO225} + 15 \ \text{CO226} + 12 \ \text{CO227} + 16 \ \text{CO228} + 18 \ \text{CO229} \\ + 13 \ \text{CO230} + 14 \ \text{CO231} + 16 \ \text{CO232} + 14 \ \text{CO233} + 15 \ \text{CO234} + 15 \ \text{CO235} \\ + 18 \ \text{CO236} + 15 \ \text{CO237} + 14 \ \text{CO238} + 13 \ \text{CO239} + 18 \ \text{CO240} \end{array}$ 

Repeat for C0002, C0003, ..., C0240

Group 2 constraints linearize the same QCs, so they too can be removed

# **Additional Simplifications**

 $n = 16, N = \{1 \dots n^2\}$ Minimize  $\sum_{i \in N} \sum_{j \in N} q'_{ij} x_i x_j$ . s.t.

<Grid constraints>

 $\sum_{i \in Gk} \sum_{j \in Gl} q_{ij} x_i x_j \geq 11$  x binary

Model is a quadratic assignment problem (QAP) except for these constraints

// bounds on objective variables that have been substituted out

We can get remove these constraints by first doing a change of variables C'I = Ci – 11 for the objective variables in the original model

#### **Generic QAP**

• After the change of variables:

 $Minimize \sum_{i=1}^{n^2} \sum_{j=1}^{n^2} q_{ij} x_i x_j$ 

s.t. 
$$\sum_{j=1}^{n} x_{kn+j} = 1 \quad k = 0, \dots, n-1$$
$$\sum_{k=0}^{n-1} x_{kn+j} = 1 \quad j = 1, \dots, n$$
$$x \in \{0, 1\}^{n^2}$$

...

Good News: It's a QAP
Take advantage of all sorts of results in the literature

#### Bad News: It's a QAP

- NP Hard
- Branch and Cut not particularly effective as size increases

### **Grid structure**

x1	x2	x3	=1
x4	x5	x6	=1
x7	x8	x9	=1
=1	=1	=1	

- 1. Only constraints in the model are the grid (e.g., QAP)
  - One to one correspondence between cliques and integer feasible solutions (Junger, Kaibel, 2001)
- 2. Additional constraints besides grid
  - Cliques may be useful for heuristics
- 3. In both cases we may be able to use the complement of the conflict graph for cuts.
  - It is a superset of the Padberg graph

Could use this to calculate the minimum number of linearization variables that must be 1

x5

x2

x3

x4

X

x6

x9

x7

x8

Conflict graph

### **Generic QAP**

- How many linearization variables must be 1?
  - SubMIP solve for case where  $Q_{ij} \ge 0$ :

$$\begin{array}{ll} \min c^{T}x + x^{T}Qx & \min c^{T}x + d^{T}z & \min e^{T}z \\ \left[s.t. \ Ax \sim b \ \right] & \left[s.t. \ Ax \sim b \ \right] & \left[s.t. \ Ax \sim b \ \right] \\ x \in \{0,1\} & E_{1}x + E_{2}z \leq p \\ x,z \in \{0,1\} & x,z \in \{0,1\} \\ \end{array}$$

- Cardinality cut:  $e^T z \ge z^*$
- Solve time for subMIP associated with reformulated QAP: 2 seconds
- Solve time for (linearized) QAP with subMIP cut (Gurobi defaults): ~34 hours, ~1800 nodes
- Solve time with NodeMethod=2 to invoke barrier at the nodes: ~8 hours, ~1300 nodes
- Time to demote the associated MIPLIB model from open to hard

#### GUROBI OPTIMIZATION

# Validation

- We solved this model with two reformulations and some strengthening
  - Change of variables
  - Reformulation from MIQCP to QAP
  - Added one cut to get the dual bound to move fast enough to solve to optimality

...

- How can we check each step?
  - We may have some skeptics in the audience with stringent requirements

@JeffLinderoth

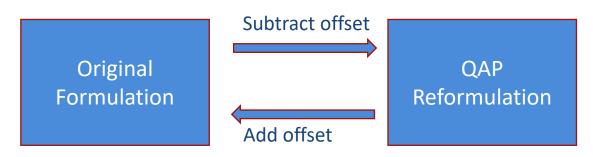

I hope they have a rational dual certificate for all leaf nodes, or else I don't believe that they solved it. And God forbid if they used any cutting-planes.

That's a pretty high bar (high jump, not limbo), but there are some simpler sanity checks we should always do

#### GUROBI OPTIMIZATION

# Validation

- Sanity check for the reformulations
  - Any solution from the reformulated QAP should have an objective 39622 (the implicit constant term removed by the reformulation) larger if used as a MIP start for the original model
    - Example: Optimal solution to the QAP:
      - 1244 0 cutoff 17 8558.00000 8541.50629 0.19% 2870 31424s
    - Add 39622 to 8558: 48180, the objective value of the QAP MIP start when given to the original formulation
    - Similar comparisons for other solutions, always consistent
    - Sorry Jeff, I didn't run the solution pool to enumerate all integer feasible solutions and test each one

# Validation

- Sanity check for primal bound
  - Feed the optimal solution with objective 48180 to the original model
  - Run with aggressive settings to find additional feasible solutions

```
>>> m.setParam("NoRelHeurTime", 10800)
Set parameter NoRelHeurTime to value 10800
>>> m.setParam("Heuristics", .5)
Set parameter Heuristics to value 0.5
>>> m.setParam("ImproveStartTime", 144000)
Set parameter ImproveStartTime to value 144000
>>> m.setParam("MIPFocus", 1)
```

- If Gurobi finds a better solution, we have an error in our reformulations or cut to investigate
  - That did not happen so far:

5602011 4148324 48119.7857	116	79 48180.0000 42200.0586	12.4%	89.7 286536s
5602481 4148966 44647.9308	60	168 48180.0000 42200.0797	12.4%	89.7 286562s
5603343 4149580 43111.6047	72	171 48180.0000 42200.1301	12.4%	89.7 286588s

#### GUROBI OPTIMIZATION

# Validation

- Sanity check for dual bound
  - The one cut we added was globally valid; it did not rely on dual based arguments
  - Reverse the direction of the cut from  $\sum z_{ij} \ge 100$  to  $\sum z_{ij} \le 99$
  - Confirm that no integer feasible solutions are found
    - So far so good:

1635016	1633989	7697.31680	59	1001
1635024	1633997	7949.39134	87	1177

#### Summary and Takeaways

© 2023 Gurobi Optimization, LLC. Confidential, All Rights Reserved | 39

### Summary

- neos-2629914-sudost can be demoted from open to hard
  - Recognize that the original MILP formulation is a linearized version of a MIQCP
  - Change of variables to remove the implicit constant term of the objective and enable more substitutions
  - Use the grid of binary variables to visualize the model and recognize a reformulation to a QAP
  - Add a cut based on a fast solving subMIP that minimizes the sum of linearization variables (for the QAP, but not for the original model)
  - But we still were somewhat fortunate that the size of the QAP wasn't bigger

## Takeaways

- MILPs may have products of binary variables in disguise
  - Models involving notion of overlap
  - Sharing info from a MILP and MIQP (and vice versa) formulation may help
- Underutilized generic structures involving binary variables
  - Complement of the conflict graph
  - Grids of binary variables with constraints on the rows and columns
- Gurobi Python API well suited to the tasks associated with model reformulation, graph constructs, tightening formulations
  - Programs used will be available at https://github.com/Gurobi/techtalks/tree/main/554 mipformulations/programs
  - Networkx Python package for graph operations
  - Other solvers and modeling language also have Python API with similar modeling constructs

### **Question from a Gurobi Tech Talk**

Which book includes the following text?

"...working out the most efficient way to pack up and down the trucks, since saving one truck ... could save something in the region of \$100,000"

- A) Mason, "Inside Out: A Personal History of Pink Floyd"
- B) Woolsey, "Real World Operations Research: The Woolsey Papers"
- C) Applegate et al., "The Traveling Salesman Problem"
- D) Davenport, "Competing on Analytics"

(https://www.gurobi.com/events/holiday-tech-talk-santas-bagof-interesting-unusual-optimization-applications/

- $Max \sum_{i < j} d_{ij} x_i x_j$   $s.t. \sum_{j=1}^n x_j = k$   $x_j \in \{0, 1\}$   $Max \sum_{i < j} d_{ij} z_{ij}$   $s.t. \sum_{j=1}^n x_j = k$ Since the set of the set of
  - $\sum_{i < j} z_{ij} = k * (k 1)/2$  $x_i \in \{0, 1\}$
  - Generic approach #1: RLT and aggregate (from the blog):
- $x_{i} * (\sum_{j=1}^{n} x_{j}) = k * x_{i}$   $x_{i} * (\sum_{j < i} x_{j} + \sum_{j > i} x_{j}) + x_{i}^{2} = k * x_{i}$   $\sum_{j < i} z_{ij} + \sum_{j > i} z_{ij} = (k 1) * x_{i}$ (add all n such constraints:  $\sum_{i=1}^{n} (\sum_{j < i} z_{ij} + \sum_{j > i} z_{ij}) = (k 1) * \sum_{i=1}^{n} x_{i}$   $\sum_{j \neq i} z_{ij} = (k 1) * k \implies 2 * \sum_{i < j} z_{ij} = k * (k 1) \implies \sum_{i < j} z_{ij} = k * (k 1)/2$

 $> x_i^2 = x_i$
